External Features of the Maize Grain

Husk (Pericarp)

The outermost layer of the maize grain is called the husk or pericarp. It acts as a protective covering, shielding the seed from physical damage, pests, and environmental factors like moisture and pathogens. The husk is composed of several leaf-like structures that encase the grain tightly during maturation.

Function: Protection and moisture regulation
Appearance: Green or dry, fibrous layer when mature

Awns and Bran

In some maize varieties, especially popcorn or ornamental types, small hair-like structures called awns protrude from the husk. These aid in seed dispersal and may have a role in protection.

Pericarp (Outer Layer)

The pericarp is the seed coat that directly envelops the kernel. It is a tough, fibrous layer that provides mechanical strength and serves as a barrier against pests and pathogens.

Function: Protects the embryo and endosperm
Implication: Affects milling and processing qualities

Cross-Sectional Anatomy of the Maize Grain

When viewing a diagram of maize grain with label, the internal structure reveals a layered complexity vital for understanding its nutritional and reproductive roles.

Endosperm

The largest component of the maize kernel, constituting approximately 83% of the grain's weight. It is a rich source of starch, providing energy for the developing seedling.

Structure: Mostly composed of starch granules embedded in protein matrix
Function: Nutrient reserve for germination

Types:

- Floury (soft) endosperm:** easily ground
- Dent endosperm:** has a depression at the top
